Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus

Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 30 December 2021, a total of 239 cases of human infection with avian influenza A(H5N1) virus have been reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%. The last case was reported from Lao PDR, with an onset date of 13 October 2020 (one case, no death).

Table 1: Cumulative number of laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO, by date of onset (January 2003 to 30 December 2021), Western Pacific Region

Globally, from January 2003 to 30 December 2021, there were 863 cases of human infection with avian influenza A(H5N1) virus reported from 18 countries. Of these 863 cases, 456 were fatal (CFR of 53%). The last case was reported from India in July 2021 (source).

Human infection with avian influenza A(H5N6) virus

Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H5N6) virus were notified to WHO in the Western Pacific Region. To date, a total of 58 laboratory-confirmed cases of human infection with influenza A(H5N6) virus including 27 deaths have been reported to WHO in the Western Pacific Region since 2014. The last case was reported from China with onset date of 3 December 2021.

Public health risk assessment for human infection with avian influenza A(H5) viruses

Whenever avian influenza viruses are circulating in poultry, there is a risk for sporadic infection and small clusters of human cases due to exposure to infected poultry or contaminated environments. Therefore, sporadic human cases are not unexpected.

The rise in numbers of reported human cases of A(H5N6) infection may reflect the continued circulation of the virus in birds, and enhanced surveillance system and diagnostic capacity as a direct outcome from the response to the COVID-19 pandemic. The zoonotic threat remains elevated due to the spread of the viruses among birds. However, the overall pandemic risk associated with A(H5) is considered not significantly changed in comparison to previous years. WHO recommends Member States to remain vigilant and consider mitigation steps to reduce human exposure to potentially infected birds to reduce the risk of additional zoonotic infections.

For information on risk assessments on Avian Influenza, visit:
Assessment of risk associated with highly pathogenic avian influenza A(H5N6) virus
Human infection with avian influenza A(H7N4) virus in China
Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H7N4) virus were reported to WHO in the Western Pacific Region. To date, only one laboratory-confirmed case of human infection with influenza A(H7N4) virus has been reported to WHO. This case was reported from China on 14 February 2018.

Human infection with avian influenza A(H7N9) virus in China
Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H7N9) virus were reported to WHO in the Western Pacific Region. To date, a total of 1,568 laboratory-confirmed human infections with avian influenza A(H7N9) virus including 616 fatal cases (CFR: 39%) have been reported to WHO since early 2013. The last case of human infection with avian influenza A(H7N9) reported to WHO in the Western Pacific Region was on 14 February 2017.

Of the 1,568 human infections with avian influenza A(H7N9), 33 have reported mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. These 33 cases were from Taiwan, China (one case had travel history to Guangdong), Guangxi, Guangdong, Hunan, Shaanxi, Hebei, Henan, Fujian, Yunnan, and Inner Mongolia. No increased transmissibility or virulence of the virus within human cases has been detected related to the HPAI A(H7N9) virus (source).

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (1 October 2016 to 30 September 2017) were greater than previous waves and the subsequent waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there is no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behaviour to humans as this may have serious public health impacts.

Human infection with avian influenza A(H9N2) virus
Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H9N2) were reported from China to WHO in the Western Pacific Region. To date, 20 cases of avian influenza A(H9N2) have been reported to WHO from China in 2021, and a total of 61 cases of human infection with avian influenza A(H9N2) including two deaths (both with underlying conditions) have been reported to WHO in the Western Pacific Region since December 2015. The last case was reported from China with onset date of 6 December 2021.

Human infection with avian influenza A(H10N3) virus
Between 24 December and 30 December 2021, no new cases of human infection with avian influenza A(H10N3) virus were reported to WHO in the Western Pacific Region. To date, one case of avian influenza A(H10N3) virus has been reported globally.
Most previously reported human infections with avian influenza viruses were due to exposure to infected poultry or contaminated environments. Since avian influenza viruses, including avian influenza A(H10N3) viruses, continue to be detected in poultry populations, further sporadic human cases could be detected in the future. Currently available epidemiologic information suggests that the avian influenza A(H10N3) virus has not acquired the ability for sustained human-to-human transmission, thus the likelihood of spread among human is low (source 1, 2).

**Animal infection with avian influenza virus**

Between 24 December and 30 December 2021, ten new outbreaks of avian influenza were reported to OIE from the Western Pacific Region. (source)

On 24 December 2021, Taiwan, China reported to OIE nine outbreaks of highly pathogenic avian influenza A(H5N2) among poultry. Outbreaks occurred in three locations; Sihu Township, Zhutang Township and Beizang Township. A total of 10,707 confirmed cases leading to 10,624 deaths were reported among 66,408 susceptible birds. The remaining 53,029 birds were culled and 2755 were killed for commercial use. (source)

On 24 December 2021, Taiwan, China reported to OIE one outbreak of highly pathogenic avian influenza A(H5N1) among wild birds. A(H5N1) was detected in two deceased wild birds in Annan District. (source).
