Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus
Between 18 March 2022 and 24 March 2022, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 24 March 2022, a total of 239 cases of human infection with avian influenza A(H5N1) virus have been reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%. The last case was reported from Lao PDR, with an onset date of 13 October 2020 (one case, no death).

Table 1: Cumulative number of laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO, by date of onset (January 2003 to 24 March 2022), Western Pacific Region

Globally, from January 2003 to 24 March 2022, there have been 863 cases of human infection with avian influenza A(H5N1) virus reported from 18 countries. Of these 863 cases, 455 were fatal (CFR of 53%). The last case was reported from India in July 2021 (source).

Human infection with avian influenza A(H5N6) virus
Between 18 March 2022 and 24 March 2022, no new cases of human infection with avian influenza A(H5N6) virus were notified to WHO in the Western Pacific Region.

To date, a total of 75 laboratory-confirmed cases of human infection with influenza A(H5N6) virus including 32 deaths have been reported to WHO in the Western Pacific Region since 2014.

Public health risk assessment for human infection with avian influenza A(H5) viruses
Whenever avian influenza viruses are circulating in poultry, there is a risk for sporadic infection and small clusters of human cases due to exposure to infected poultry or contaminated environments. Therefore, sporadic human cases are not unexpected.

The rise in numbers of reported human cases of A(H5N6) infection may reflect the continued circulation of the virus in birds, and enhanced surveillance system and diagnostic capacity as a direct outcome from the response to the COVID-19 pandemic. The zoonotic threat remains elevated due to the spread of the viruses among birds. However, the overall pandemic risk associated with A(H5) is considered not significantly changed in comparison to previous years. WHO recommends Member States to remain vigilant and consider mitigation steps to reduce human exposure to potentially infected birds to reduce risk of additional zoonotic infection.

Assessment of risk associated with highly pathogenic avian influenza A(H5N6) virus
Human infection with avian influenza A(H7N4) virus in China
Between 18 March 2022 and 24 March 2022, no new cases of human infection with avian influenza A(H7N4) virus were reported to WHO in the Western Pacific Region. To date, only one laboratory-confirmed case of human infection with influenza A(H7N4) virus has been reported to WHO. This case was reported from China on 14 February 2018.

Human infection with avian influenza A(H7N9) virus in China
Between 18 March 2022 and 24 March 2022, no new cases of human infection with avian influenza A(H7N9) virus were reported to WHO in the Western Pacific Region. To date, a total of 1,568 laboratory-confirmed human infections with avian influenza A(H7N9) virus including 616 fatal cases (CFR: 39%) have been reported to WHO since early 2013. The last case of human infection with avian influenza A(H7N9) reported to WHO in the Western Pacific Region was in 2019.

Of the 1,568 human infections with avian influenza A(H7N9), 33 have reported mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. These 33 cases were from Taiwan, China (one case had travel history to Guangdong), Guangxi, Guangdong, Hunan, Shaanxi, Hebei, Henan, Fujian, Yunnan, and Inner Mongolia. No increased transmissibility or virulence of the virus within human cases has been detected related to the HPAI A(H7N9) virus (source).

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (1 October 2016 to 30 September 2017) were greater than previous waves and the subsequent waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighboring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there is no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behavior to humans as this may have serious public health impacts.

Human infection with avian influenza A(H9N2) virus
Between 18 March 2022 and 24 March 2022, one case of human infection with avian influenza A(H9N2) was reported from Cambodia to WHO in the Western Pacific Region.

The case is a 13-month-old female from Chi Kreng district, Siem Reap province, Cambodia. The case has no underlying conditions; symptoms of runny nose and cough began on 27 February and as the case did not improve, she was admitted to Angkor Hospital for Children (AHC) on 3 March. She had mild dyspnea, fever (>38 °C), cough and sore throat on admittance. She improved overnight and was discharged on 4 March.

No symptoms in the rest of the family had been observed, but many children in the village were observed with Influenza-Like Illness (ILI) symptoms. Nasal swabs were collected from thirteen family members and close contacts from the village; none tested positive for influenza. Some poultry in the village were sick/died in the last couple of months and each family keep chickens in the backyard, including where the case lived. Sixteen chicken samples were collected from five households including that of the index case. Four samples, all from the case household, were positive for avian influenza A/H9N2.
This is the second human influenza A(H9N2) detection in Cambodia. Previously, one A(H9N2) case, a three-year-old boy also from the Siem Reap Province and with mild illness has been reported to WHO on 17 March 2021.

To date, a total of 74 cases of human infection with avian influenza A(H9N2) including two deaths (both with underlying conditions) have been reported to WHO in the Western Pacific Region since December 2015.

**Human infection with avian influenza A(H10N3) virus**

Between 18 March 2022 and 24 March 2022, no new cases of human infection with avian influenza A(H10N3) virus were reported to WHO in the Western Pacific Region. To date, one case of avian influenza A(H10N3) virus has been reported globally.

Most previously reported human infections with avian influenza viruses were due to exposure to infected poultry or contaminated environments. Since avian influenza viruses, including avian influenza A(H10N3) viruses, continue to be detected in poultry populations, further sporadic human cases could be detected in the future. Currently available epidemiologic information suggests that the avian influenza A(H10N3) virus has not acquired the ability for sustained human-to-human transmission, thus the likelihood of spread among human is low (source 1, 2).

**Animal infection with avian influenza virus**

Between 18 March 2022 and 24 March 2022, four new reports of outbreaks of avian influenza among birds were reported to OIE from the Western Pacific Region (source).

On 18 March 2022, Japan reported to OIE about highly pathogenic avian influenza A(H5) in 1 case of wild bird leading to 1 death in Nihonmatsu in Fukushima province (source).

On 21 March 2022, Japan reported to OIE twenty-eight outbreaks of highly pathogenic avian influenza A(H5N1) among wild birds in Kuji in Iwate prefecture and Shibetsu, Nemuro in Hokkaido. In total, there were 67 cases leading to 67 deaths (source).

On 23 March 2022, Philippines reported to OIE 1 outbreak of highly pathogenic avian influenza A(H5N8) among poultry in Santa Ana in Pampanga Province. In total, there were 10 cases leading to no deaths among 2,730 susceptible birds (source).

On 23 March 2022, Philippines reported to OIE sixteen outbreaks of highly pathogenic avian influenza A(H5N1) among poultry in Guimba, Cuyapo, Muñoz City, Aliaga, and Santo Domingo in Nueva Ecija Province; Bula, Balatan, Libmanan, Nabua, Goa, and Baao in Camarines Sur Province; San Pedro and Victoria in Laguna Province; Hermosa in Bataan Province; La Paz in Tarlac Province. In total, there were 15,937 cases leading to 15,899 deaths among 2,0831 susceptible birds, and the remaining 4,906 poultry were culled (source).
