OVERVIEW

Brunei Darussalam is a nation located on the north-west coast of Borneo in Southeast Asia. It is separated by the East Malaysian state of Sarawak into a western part (Brunei-Muara, Tutong and Belait districts) and an eastern part (Temburong district). Brunei Darussalam has a total land area of 5,765 square km with the capital, Bandar Seri Begawan, located at Brunei-Muara district [Brunei Darussalam Economic Planning and Development Department, 2015].

With an equatorial climate, it is generally hot and wet throughout the year with the heaviest rainfall period from October to January and May to July [Brunei Darussalam Meteorological Department, 2016]. Brunei is highly vulnerable to the impacts of climate change, with risks of increased flooding, heat-related mortality, occupational health hazards and water scarcity alongside reduced agricultural production [Brunei Darussalam’s INDC, 2015].

The national vision of Brunei Darussalam is called Wawasan Brunei 2035, which outlines the social, economic and environmental goals for the country. Enhancing climate resilience, adaptation and mitigation measures are considered necessary to protect the health and well-being of the population as well as the country’s natural resources. To this end, the government has identified 6 priority sectors for further climate change adaptation actions: 1) Biodiversity, 2) Forestry, 3) Coastal and flood protection, 4) Health, 5) Agriculture and 6) Fisheries [Brunei Darussalam’s INDC, 2015].

SUMMARY OF KEY FINDINGS

• In Brunei Darussalam, under a high emissions scenario, mean annual temperature is projected to rise by about 3.9°C on average from 1990 to 2100. If global emissions decrease rapidly, the temperature rise is limited to about 1.1°C [page 2].

• In Brunei Darussalam, under a high emissions scenario heat-related deaths in the elderly (65+ years) are projected to increase to about 51 deaths per 100,000 by 2080 compared to the estimated baseline of zero deaths per 100,000 annually between 1961 and 1990. A rapid reduction in global emissions could limit heat-related deaths in the elderly to about 7 deaths per 100,000 in 2080 [page 4].

OPPORTUNITIES FOR ACTION

Brunei Darussalam has a national health adaptation strategy and is currently implementing projects on health adaptation to climate change. Adaptation activities include several programs to combat vector-borne diseases, efforts to strengthen climate-sensitive disease surveillance and response and awareness raising activities with healthcare professionals and the public. Country reported data [section 6] indicate further opportunities for action in the following areas:

1) Adaptation
• Conduct a national assessment of climate change impacts, vulnerability and adaptation for health.
• Continue to expand activities to increase climate resilience of health infrastructure beyond vector-borne disease preparedness.
• Further develop cost estimates and allocations, beyond vector surveillance and control, to include all adaptation activities necessary to implement health resilience to climate change.

2) Mitigation
• Conduct a valuation of the health co-benefits of climate change mitigation policies.

3) National Policy Implementation
• Develop a national health strategy for climate change mitigation that considers the health implications of climate change mitigation actions.

DEMOGRAPHIC ESTIMATES*

| Population (2013)*                  | 411.50 thousand |
| Population growth rate (2013)*      | 1.4 %           |
| Population living in urban areas (2013)* | 76.6 %     |
| Population under five (2013)*       | 7.8 %           |
| Population aged 65 or over (2013)*  | 4.0 %           |

ECONOMIC AND DEVELOPMENT INDICATORS

| GDP per capita (current US$, 2013)*                 | 36,608 USD     |
| Total expenditure on health as % of GDP (2013)*   | 2.5 %           |
| Percentage share of income for lowest 20% of population (2010)* | NA |
| HDI (2013, +/- 0.01 change from 2005 is indicated with arrow)* | 0.852 ▲ |

HEALTH ESTIMATES

| Life expectancy at birth (2013)*                  | 77 years       |
| Under-5 mortality per 1000 live births (2013)*    | 10             |

---

* The estimates and indicators provided in this table may not be regarded as the nationally endorsed statistics of Member States. For recent national estimates please see: Brunei Darussalam Key Indicators [BDKI] 12- Annual 2015, Department of Economic Planning and Development, Prime Minister’s Office, Brunei Darussalam [2015] or Health Information Booklet 2015, Office of Policy and Foresight, Ministry of Health, Brunei Darussalam [2015].
Due to climate change, many climate hazards and extreme weather events, such as heat waves, heavy rainfall and droughts, could become more frequent and more intense in many parts of the world. Outlined here are country-specific projections up to the year 2100 for climate hazards under a ‘business as usual’ high emissions scenario compared to projections under a ‘two-degree’ scenario with rapidly decreasing global emissions. Most hazards caused by climate change will persist for many centuries.

**COUNTRY-SPECIFIC CLIMATE HAZARD PROJECTIONS**

The model projections below present climate hazards under a high emissions scenario, Representative Concentration Pathway 8.5 [RCP8.5] (in orange) and a low emissions scenario, [RCP2.6] (in green).\(^a\) The text boxes describe the projected changes averaged across about 20 models (thick line). The figures also show each model individually as well as the 90% model range (shaded) as a measure of uncertainty and, where available, the annual and smoothed observed record (in blue).\(^b\c\)

**MEAN ANNUAL TEMPERATURE**

Under a high emissions scenario, mean annual temperature is projected to rise by about 3.9°C on average from 1990 to 2100. If global emissions decrease rapidly, the temperature rise is limited to about 1.1°C.

**DAYS OF WARM SPELL (‘HEAT WAVES’)**

Under a high emissions scenario, the number of days of warm spell\(^d\) is projected to increase from about 15 days in 1990 to about 320 days on average in 2100. If global emissions decrease rapidly, the days of warm spell are limited to about 110 on average.

**DAYS WITH EXTREME RAINFALL (‘FLOOD RISK’)**

Under a high emissions scenario, the number of days with very heavy precipitation (20 mm or more) could increase by about 7 days on average from 1990 to 2100, increasing the risk of floods. A few models indicate increases well outside the range of historical variability, implying even greater risk. If global emissions decrease rapidly, the increase in risk is much reduced.

**CONSECUTIVE DRY DAYS (‘DROUGHT’)**

Under both high and low emissions scenarios, the longest dry spell is not indicated to change much from an average of about 15 days, with continuing large year-to-year variability.

---

\(^a\) Model projections are from CMIP5 for RCP8.5 [high emissions] and RCP2.6 [low emissions]. Model anomalies are added to the historical mean and smoothed.

\(^b\) Observed historical record of mean temperature is from CRU-Tsv.3.22.

\(^c\) Analysis by the Climatic Research Unit and Tyndall Centre for Climate Change Research, University of East Anglia, 2015.

\(^d\) A ‘warm spell’ day is a day when maximum temperature, together with that of at least the 6 consecutive previous days, exceeds the 90th percentile threshold for that time of the year.
Human health is profoundly affected by weather and climate. Climate change threatens to exacerbate today’s health problems – deaths from extreme weather events, cardiovascular and respiratory diseases, infectious diseases and malnutrition – whilst undermining water and food supplies, infrastructure, health systems and social protection systems.

Under a high emissions scenario, and without large investments in adaptation, an annual average of 2,000 people are projected to be affected by flooding due to sea level rise between 2070 and 2100. If global emissions decrease rapidly and there is a major scale up in protection (i.e. continued construction/raising of dikes) the annual affected population could be limited to less than 100 people. Adaptation alone will not offer sufficient protection, as sea level rise is a long-term process, with high emissions scenarios bringing increasing impacts well beyond the end of the century.

In addition to deaths from drowning, flooding causes extensive indirect health effects, including impacts on food production, water provision, ecosystem disruption, infectious disease outbreak and vector distribution. Longer term effects of flooding may include post-traumatic stress and population displacement.

In Brunei Darussalam, under a high emissions scenario, the mean relative vectorial capacity for dengue fever transmission is projected to increase to about 1.24 towards 2070 from a mean baseline value of about 0.92 between 1961 to 1990. If global emissions decline rapidly, the mean relative vectorial capacity towards 2070 would be about 1.15.

Source: Rocklöv, J., Quam, M. et al., 2015.a

Some of the world’s most virulent infections are also highly sensitive to climate: temperature, precipitation and humidity have a strong influence on the life-cycles of the vectors and the infectious agents they carry and influence the transmission of water and food-borne diseases. b

Socioeconomic development and health interventions are driving down burdens of several infectious diseases, and these projections assume that this will continue. However, climate conditions are projected to become significantly more favourable for transmission, slowing progress in reducing burdens, and increasing the populations at risk if control measures are not maintained or strengthened. c

---

a Country-level analysis, completed in 2015, was based on health models outlined in the Quantitative risk assessment of the effects of climate change on selected causes of death, 2030s and 2050s. Geneva: World Health Organization, 2014. The mean of impact estimates for three global climate models are presented. Models assume continued socioeconomic trends (SSP2 or comparable).

Climate change is expected to increase mean annual temperature and the intensity and frequency of heat waves resulting in a greater number of people at risk of heat-related medical conditions. The elderly, children, the chronically ill, the socially isolated and at-risk occupational groups are particularly vulnerable to heat-related conditions.

In Brunei Darussalam, under a high emissions scenario, heat-related deaths in the elderly (65+ years) are projected to increase to about 51 deaths per 100,000 by 2080 compared to the estimated baseline of zero deaths per 100,000 annually between 1961 and 1990. A rapid reduction in global emissions could limit heat-related deaths in the elderly to about 7 deaths per 100,000 in 2080.

Source: Honda et al., 2015.a

Climate change, through higher temperatures, land and water scarcity, flooding, drought and displacement, negatively impacts agricultural production and causes breakdown in food systems. These disproportionately affect those most vulnerable people at risk to hunger and can lead to food insecurity. Vulnerable groups risk further deterioration into food and nutrition crises if exposed to extreme climate events.b

Without considerable efforts made to improve climate resilience, it has been estimated that the global risk of hunger and malnutrition could increase by up to 20 percent by 2050.b

CURRENT EXPOSURES AND HEALTH RISKS DUE TO AIR POLLUTION

Many of the drivers of climate change, such as inefficient and polluting forms of energy and transport systems, also contribute to air pollution. Air pollution is now one of the largest global health risks, causing approximately seven million deaths every year. There is an important opportunity to promote policies that both protect the climate at a global level, and also have large and immediate health benefits at a local level.

OUTDOOR AIR POLLUTION EXPOSURE

Outdoor air pollution in cities in Brunei Darussalam
annual mean PM$_{2.5}$ [μg/m$^3$] 2010$	extsuperscript{*}$

The cities for which there was air pollution data available had annual mean PM$_{2.5}$ levels that were below the WHO guideline value of 10 μg/m$^3$.

Source: Ambient Air Pollution Database, WHO, May 2014. * A standard conversion has been used, see source for further details.

KEY IMPLICATIONS FOR HEALTH

Outdoor air pollution can have direct and sometimes severe consequences for health.

Fine particles which penetrate deep into the respiratory tract subsequently increase mortality from respiratory infections, lung cancer and cardiovascular disease.
CO-BENEFITS TO HEALTH FROM CLIMATE CHANGE MITIGATION: A GLOBAL PERSPECTIVE

Health co-benefits are local, national and international measures with the potential to simultaneously yield large, immediate public health benefits and reduce the upward trajectory of greenhouse gas emissions. Lower carbon strategies can also be cost-effective investments for individuals and societies.

Presented here are examples, from a global perspective, of opportunities for health co-benefits that could be realised by action in important greenhouse gas emitting sectors.

<table>
<thead>
<tr>
<th>Transport</th>
<th>Electricity Generation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transport injuries lead to 1.2 million deaths every year, and land use and transport planning contribute to the 2–3 million deaths from physical inactivity. The transport sector is also responsible for some 14% (7.0 GtCO₂e) of global carbon emissions. The IPCC has noted significant opportunities to reduce energy demand in the sector, potentially resulting in a 15%–40% reduction in CO₂ emissions, and bringing substantial opportunities for health: A modal shift towards walking and cycling could see reductions in ill health related to physical inactivity and reduced outdoor air pollution and noise exposure; increased use of public transport is likely to result in reduced GHG emissions; compact urban planning fosters walkable residential neighborhoods, improves accessibility to jobs, schools and services and can encourage physical activity and improve health equity by making urban services more accessible to the elderly and poor.</td>
<td>Reliable electricity generation is essential for economic growth, with 1.4 billion people living without access to electricity. However, current patterns of electricity generation in many parts of the world, particularly the reliance on coal combustion in highly polluting power plants contributes heavily to poor local air quality, causing cancer, cardiovascular and respiratory disease. Outdoor air pollution is responsible for 3.7 million premature deaths annually, 88% of these deaths occur in low and middle income countries. The health benefits of transitioning from fuels such as coal to lower carbon sources, including ultimately to renewable energy, are clear. Reduced rates of cardiovascular and respiratory disease such as stroke, lung cancer, coronary artery disease, and COPD; cost-savings for health systems; improved economic productivity from a healthier and more productive workforce.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Food and Agriculture</th>
<th>Healthcare Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agricultural emissions account for some 5.0–5.8 GtCO₂eq annually, with food and nutrition constituting an important determinant of health. Many high-income countries are feeling the burden of poor diet and obesity-related diseases, with some 1.9 billion adults overweight globally. A wide range of interventions designed to reduce emissions from agriculture and land-use will also yield positive benefits for public health. For example, policy and behavioural interventions to encourage a reduction in red meat consumption and a shift towards local and seasonal fruit and vegetables, which tend to have lower carbon emissions associated with their production, will improve diets and result in reductions in cardiovascular disease and colorectal cancer.</td>
<td>Health care activities are an important source of greenhouse gas emissions. In the US and in EU countries, for example, health care activities account for between 3–8% of greenhouse gas (CO₂-eq) emissions. Major sources include procurement and inefficient energy consumption. Modern, on-site, low-carbon energy solutions (e.g. solar, wind, or hybrid solutions) and the development of combined heat and power generation capacity in larger facilities offer significant potential to lower the health sector’s carbon footprint, particularly when coupled with building and equipment energy efficiency measures. Where electricity access is limited and heavily reliant upon diesel generators, or in the case of emergencies when local energy grids are damaged or not operational, such solutions can also improve the quality and reliability of energy services. In this way, low carbon energy for health care could not only mitigate climate change, it could enhance access to essential health services and ensure resilience.</td>

EMISSIONS AND COMMITMENTS

Global carbon emissions increased by 80% from 1970 to 2010, and continue to rise.a,b Collective action is necessary, but the need and opportunity to reduce greenhouse gas emissions varies between countries. Information on the contribution of different sectors, such as energy, manufacturing, transport and agriculture, can help decision-makers to identify the largest opportunities to work across sectors to protect health, and address climate change.

Brunei Darussalam is in the process of developing its Initial National Communication (INC). The following extract from Brunei Darussalam’s Intended Nationally Determined Contribution (INDC), November, 2015, provides an estimate of national emissions that will be reported in a Greenhouse Gas (GHG) emissions inventory:

"The draft INC estimates that in 2010 Brunei Darussalam’s GHG emissions were approximately 10.02 million tonnes of CO₂ equivalent (Mt CO₂eq). It is also estimated that land-use change and forestry (LUCF) contributes to the removal of 2.63 million tonnes equivalent CO₂ sequestration. The net GHG emissions were approximately 7.40 million tonnes of CO₂ equivalent. This total represents a small fraction of global emissions; approximately 0.016% of global emissions in 2010.

The GHG emissions arising in Brunei Darussalam are dominated by sources in the energy sector. Electricity generation is the largest source of GHG emissions. Currently, around 99% of the country’s electricity is generated from natural gas,d of which the majority comes from open cycle power plants [...]. Energy production, including the production of oil and gas for domestic and exports markets, is another important source. Emissions from this sector were estimated to be 3.11 Mt CO₂eq in 2010. GHG emissions also arise from the direct combustion of fossil fuels in end-use sectors. Of these sources, fuel consumption in transport is responsible for approximately 1.17 Mt CO₂eq, with emissions from energy consumption in industry responsible for 0.45 Mt CO₂eq."

"Brunei Darussalam's planned mitigation efforts are focused primarily on energy related policies and actions, promoting energy efficiency and conservation and renewable energy as examples." Brunei Darussalam is targeting a 63% reduction in total energy consumption by 2035 and also further aspires to generate at least 10% of total power from new and renewable resources by 2035 [Brunei Darussalam’s INDC, 2015].
