Human infection with avian influenza A(H5) viruses

Human infection with avian influenza A(H5N1) virus

Between 29 January and 4 February 2021, no new cases of human infection with avian influenza A(H5N1) virus were reported to WHO in the Western Pacific Region.

As of 4 February 2021, a total of 239 cases of human infection with avian influenza A(H5N1) virus have been reported from four countries within the Western Pacific Region since January 2003 (Table 1). Of these cases, 134 were fatal, resulting in a case fatality rate (CFR) of 56%. The last case was reported from Lao PDR, with an onset date of 13 October 2020 (one case, no death).

Table 1: Cumulative number of laboratory-confirmed human cases (C) and deaths (D) of influenza A(H5N1) virus infection reported to WHO, by date of onset (January 2003 to 4 February 2021), Western Pacific Region.

Globally, from January 2003 to 4 February 2021, there were 862 cases of human infection with avian influenza A(H5N1) virus reported from 17 countries. Of these 862 cases, 455 were fatal (CFR of 53%). The last case was reported from Lao PDR on 13 October 2020 (source).

Human infection with avian influenza A(H5N6) virus

On 24 January 2021, two new cases of human infection with avian influenza A(H5N6) virus were reported to WHO in the Western Pacific Region. The first case is a three-year-old female from Guizhou Province, China who was admitted to hospital with severe illness and died on 22 December 2020. The second case is a one-year-old female from Anhui Province, China who developed mild illness in December 2020. Both cases were sporadic and had exposure to poultry at markets prior to onset of illness. To date, a total of 29 laboratory-confirmed cases of human infection with influenza A(H5N6) virus including nine deaths have been reported to WHO from China since 2014.

Public health risk assessment for human infection with avian influenza A(H5) viruses

Whenever avian influenza viruses are circulating in poultry, there is a risk for sporadic infection and small clusters of human cases due to exposure to infected poultry or contaminated environments. Therefore, sporadic human cases are not unexpected.

With continued incidence of avian influenza due to existing and new influenza A(H5) viruses in poultry, there is a need to remain vigilant in the animal and public health sectors. Community awareness of the potential dangers for human health is essential to prevent infection in humans. Surveillance should be continued to detect human cases and early changes in transmissibility and infectivity of the viruses.

For more information on confirmed cases of human infection with avian influenza A(H5) virus reported to WHO, visit: [http://www.who.int/influenza/human_animal_interface/en/](http://www.who.int/influenza/human_animal_interface/en/)

For information on monthly risk assessments on Avian Influenza, visit: [http://www.who.int/influenza/human_animal_interface/HAI_Risk_Assessment/en/](http://www.who.int/influenza/human_animal_interface/HAI_Risk_Assessment/en/)
Human infection with avian influenza A(H7N4) virus in China

Between 29 January and 4 February 2021, no new cases of human infection with avian influenza A(H7N4) virus were reported to WHO in the Western Pacific Region. To date, only one laboratory-confirmed case of human infection with influenza A(H7N4) virus has been reported to WHO. This case was reported from China on 14 February 2018.

Human infection with avian influenza A(H7N9) virus in China

Between 29 January and 4 February 2021, no new cases of human infection with avian influenza A(H7N9) virus were reported to WHO in the Western Pacific Region. As of 4 February 2021, a total of 1,568 laboratory-confirmed human infections with avian influenza A(H7N9) virus have been reported to WHO since early 2013. Among them, 33 cases were infected with HPAI A(H7N9) virus, which have mutations in the hemagglutinin gene indicating a change to high pathogenicity in poultry. These 33 cases were from Taiwan, China (the case had travel history to Guangdong), Guangxi, Guangdong, Hunan, Shaanxi, Hebei, Henan, Fujian, Yunnan, and Inner Mongolia. No increased transmissibility or virulence of the virus within human cases has been detected related to the HPAI A(H7N9) virus (source).

WHO is continuing to assess the epidemiological situation and will conduct further risk assessments as new information becomes available. The number and geographical distribution of human infections with avian influenza A(H7N9) viruses in the fifth epidemic wave (1 October 2016 to 30 September 2017) was greater than previous waves and the subsequent waves.

Further sporadic human cases of avian influenza A(H7N9) virus infection are expected in affected and possibly neighbouring areas. Should human cases from affected areas travel internationally, their infection may be detected in another country during or after arrival. However, if this were to occur, community level spread is considered unlikely as the virus does not have the ability to transmit easily among humans.

To date, there is no evidence of sustained human-to-human transmission of avian influenza A(H7N9) virus. Human infections with the A(H7N9) virus are unusual and need to be monitored closely in order to identify changes in the virus and transmission behaviour to humans as this may have serious public health impacts.

Human infection with avian influenza A(H9N2) in China

Between 29 January and 4 February 2021, no new cases of human infection with avian influenza A(H9N2) virus were reported in the Western Pacific Region. A total of 43 cases of human infection with avian influenza A(H9N2) in China have been reported since December 2015.
Animal infection with avian influenza virus

Between 29 January and 4 February 2021, 17 new outbreaks of avian influenza were reported to OIE from the Western Pacific Region.

Highly pathogenic avian influenza virus A(H5N8) in the Republic of Korea

On 29 January, 14 new outbreaks of highly pathogenic avian influenza A(H5N8) among poultry were reported to OIE from the Republic of Korea. The outbreaks were reported in five different provinces: Gyeonggi, Chungcheongbuk, Chungcheongnam, Jeollanam, and Jeollabuk. There were 1,993 fatal cases identified among two million susceptible birds. All remaining birds were culled. (Source)

Highly pathogenic avian influenza virus A(H5N5) in Taiwan, China

On 1 February 2021, one new outbreak of highly pathogenic avian influenza A(H5N5) among poultry was reported to OIE from Taiwan, China. The outbreak occurred at a farm in Jiuru Township, Pingtung County where there were 9,222 susceptible birds. Among these, 1,697 cases were reported, resulting in 1,697 deaths. All remaining birds were culled. (Source)

Highly pathogenic avian influenza virus A(H5N8) in Hong Kong SAR, China

On 3 February 2021, one new case of highly pathogenic avian influenza A(H5N8) detected in one wild bird was reported to OIE from Hong Kong SAR, China. The virus was detected in a dead peregrine falcon collected in Lake Silver, Sha Tin District on 28 January 2021. No spread of disease was evident, and there are no poultry farms within a three kilometre radius of the site where the bird was found. (Source)

Highly pathogenic avian influenza virus A(H5N8) in China

On 3 February 2021, one new outbreak of highly pathogenic avian influenza A(H5N8) among wild birds was reported to OIE from China. The infected black swans were identified in Yuanmingyuan Ruins Park, Haidian District in Beijing. Among 15 susceptible birds identified in the area, three cases were reported, all of which had died and none of the remaining birds were culled. (Source)

Other updates

- WHO Risk Assessment of human infection with avian influenza A virus. 9 December 2020
  - Risk assessment summary: The overall public health risk from currently known influenza viruses at the human-animal interface has not changed, and the likelihood of sustained human-to-human transmission of these viruses remains low. Human infections with viruses of animal origin are expected at the human-animal interface wherever these viruses circulate in animals.
