This report was prepared by Dr Angela de Silva, Regional Adviser for Nutrition and Health for Development, and Dr Manju Rani, Regional Adviser for NCD Governance, Policy and Surveillance, from the Department of Healthier Populations and Noncommunicable Diseases, World Health Organization (WHO) Regional Office for South-East Asia. Ms Yvonne Xiru Xu, consultant, was responsible for data extraction, analysis and graphics, while Mr Naveen Agarwal provided data support.

Review comments were received from Dr Nilmini Hemachandra, WHO Regional Office for the Eastern Mediterranean, Dr Rachita Gupta, WHO Country Office, India and Dr Dinesh Jeyakumaran, WHO Country Office, Myanmar.
The double burden of malnutrition: priority actions on ending childhood obesity

Foreword

The work of WHO and its Member States in the South-East Asia Region to address the multiple forms of malnutrition affecting populations is more urgent than ever. Though Member States have in recent years made notable progress in implementing the Region’s Strategic Action Plan to reduce the double burden of malnutrition 2016-2025, accelerated action is needed.

This technical report provides a detailed picture of the double burden of malnutrition in children across the Region with the aim of supporting countries to sustain and accelerate action to tackle the problem. The data collated in the report show that overweight, obesity and the early onset of noncommunicable diseases (NCDs) are no longer adult challenges. Rather, children at younger ages are showing increasing trends of overweight and obesity. Levels of undernutrition – which is linked to overweight and obesity later in life – have been slow to decline.

In supporting countries to address the double burden of malnutrition, this report highlights the value of applying WHO-recommended double-duty actions. Double-duty actions are actions that are often already used to address single forms of malnutrition, but which have the potential to address multiple forms of malnutrition simultaneously. The double-duty actions advocated for in this report are aligned with the Region’s Strategic Action Plan and aim to harness the synergetic potential of policies, programmes and interventions to address both undernutrition and obesity, as well as dietary risk factors for NCDs.

In line with the double-duty approach, countries should develop common programme packages for obesity and overweight that can be integrated into programmes that currently focus on undernutrition and micronutrient deficiencies. Special efforts should be made to include overweight and obesity considerations in the provision of quality maternal and antenatal care and diets; support breastfeeding and ensure optimum complementary feeding for young children; and promote healthy diets in older children and adolescents, along with adequate physical activity across all age groups. Multisectoral interventions, especially those which address the food environment, will help optimize the impact of these and other measures and achieve sustainable progress.

The double burden of malnutrition has complex causes and requires careful and sustained attention and action. WHO will continue to support countries and partners in the Region to scale up evidence-based interventions that will achieve lasting gains, in line with the Region’s Flagship Priority on preventing and controlling noncommunicable diseases through high-impact “best buys”. Together we can achieve a Region in which every child can grow up healthy and strong, and into adults that have sufficient and appropriate nutrition to stay health and well throughout the life-course.

Dr Poonam Khetrapal Singh
Regional Director
WHO South-East Asia Region

Glossary

**Adolescents**
Children and young people between 10 and 19 years of age

**BMI-for-age**
BMI adjusted for age, standardized for children

**Children**
Those less than 18 years of age

**Body mass index**
Calculation: weight (kg)/height (m2). For adults, overweight is defined as a BMI ≥ 25 kg/m2 and obesity as a BMI ≥ 30 kg/m2. For children, overweight (+1SD) is equivalent to a BMI of 25 kg/m2 at 19 years of age, and obesity (+2SD) is equivalent to a BMI of 30 kg/m2 at 19 years of age

**DALY**
DALYs for a disease or health condition are calculated as the sum of the years of life lost due to premature mortality in the population, while the years lost due to disability refer to people living with health conditions or their consequences

**Double-duty actions**
Double-duty actions include interventions, programmes and policies that have the potential to simultaneously reduce the risk or burden of both undernutrition (including wasting, stunting and micronutrient deficiency or insufficiency) and overweight, obesity or diet-related noncommunicable diseases (including type 2 diabetes, cardiovascular disease and some cancers)

**Infants**
Those less than 12 months of age

**Obesogenic environment**
An environment that promotes high energy intake and sedentary behaviour. This includes the foods that are available, affordable, accessible and promoted; opportunities for physical activity; and the social norms in relation to food and physical activity

**Overweight and obesity**
Excessive fat accumulation that presents a risk to health

**Young children**
Those less than 5 years of age

---

1 Convention on the Rights of the Child, Treaty Series, 1577:3(1989): PART I, Article 1 defines a child as every human being below the age of 18 years unless, under the law applicable to the child, majority is attained earlier. The World Health Organization (WHO) defines adolescents as those between 10 and 19 years of age. The majority of adolescents are, therefore, included in the age-based definition of "child", adopted by the Convention on the Rights of the Child, as a person under the age of 18 years.
Children in WHO South-East Asia Region bear a disproportionate burden of the global problem of malnutrition.

- According to estimates, globally there are 144 million stunted, 47 million wasted and 38 million overweight children under 5 years of age. The WHO South-East Asia Region bears much of this burden, with 52 million children stunted (a third of the global burden), 25 million wasted (half of global wasting) and 5 million overweight (one-seventh of global overweight). Around 24.2% children are born with a low birth weight.

- An estimated 7.4% children (38.4 million) of 5–19 years of age in the Region are overweight in 2020, and 22.5% are thin.

- The trend of overweight among children has been rising rapidly across all age groups since 2000, while there has been a slow decline in stunting. Trends in wasting have remained stagnant in most countries.

A double burden of malnutrition exists in the Region at the population, household and individual levels.

- A double burden of malnutrition exists at the population, household and individual levels in all countries. This includes overweight mothers and stunted children and children who are both stunted and overweight. The current proportion of overweight children under 5 years of age who were also stunted was 15.2% in Thailand and 73% in Timor-Leste.

Considerable sociodemographic variations in malnutrition status are seen across countries.

- The estimated prevalence of overweight is higher among older children than among those under 5 years of age.

- Substantial intercountry variation in the prevalence of overweight is a key feature among children under 5 years of age. The current prevalence of overweight ranges from 8.2% in Thailand and 8.1% in Indonesia to 1.6% in India, 1.4% in Myanmar and 1.2% in Nepal. (Latest National data) Stunting and wasting present a mixed picture, being lower in Thailand and Maldives than in other countries.

- Child overweight is more prevalent among higher income groups and in urban areas, while the prevalence of stunting and thinness is higher in low socioeconomic groups. However, data indicate that overweight is emerging in low-income groups as well.

- Across countries, the prevalence of child overweight and obesity is similar in males and females at any age, except in Maldives (under 5 years of age) and Bhutan (age group of 15–19 years).
The Global Nutrition Targets and Sustainable Development Goal targets are unlikely to be achieved by most Member States.

- The consistent increasing trends in overweight, which have been accelerating since 2010, pose a challenge to the efforts of almost all countries to achieve the Global Nutrition Target 4: halt the increase in overweight in children (under 5 years of age).
- Most countries are also unlikely to achieve the global target or national targets set for stunting and wasting.

The burden of malnutrition is driven by biological, socioeconomic, cultural and environmental factors.

- Globalization and urbanization are driving changes in the food environment and lifestyles in the Region. Unhealthy food environments, poor diets and sedentary lifestyles place many children on the pathway to obesity and enhanced risk of noncommunicable diseases (NCD).
- The high prevalence of low birth weight and stunting are also risk factors for obesity and NCDs, with their effects being compounded by unhealthy diets.
- The different forms of malnutrition share certain biological, socioeconomic and environmental determinants. This suggests that shared pathways could be identified for prevention strategies.

Countries should enhance policy measures to simultaneously address undernutrition, overweight and obesity.

- Multisectoral policies and plans in countries usually focus on undernutrition. Broader policy measures to include interventions to address childhood overweight/obesity are required urgently.
- Policies and programmes that focus on improving nutrition during early life and throughout the life-course are of paramount importance. Simultaneously, there is a need to promote and support policies that facilitate the existence of an optimum food and physical environment.

Accurate and timely information is required to create awareness of the double burden and to inform evidence-based interventions.

- The scarcity of regular anthropometric and implementation of dietary data on children, especially in the age group of 5–9 years, is a major barrier to the development of context-specific responses to child overweight.
- Member States must take policy decisions on collecting, analysing and interpreting national-level anthropometric and relevant dietary data on children of the age of 5–19 years, and concurrently gather information regarding the food environment.
The double burden of malnutrition: priority actions on ending childhood obesity

The WHO South-East Asia Region\(^2\) are home to more than one-third (52.6 million of 144.0 million) of stunted children and more than half of wasted children under 5 years of age (24.9 million out of 47.0 million) worldwide (1). Almost a quarter of infants are born with a low birth weight (24.2\%) and micronutrient deficiencies are common (2, 3).\(^3\) The Region is now faced with a further complication in the form of rising levels of childhood overweight and obesity, with 5 million children (under 5 years of age) suffering from these conditions (1). This double burden of malnutrition is characterized by the coexistence of undernutrition, micronutrient deficiencies, overweight, obesity or diet-related NCDs within individuals, households and populations, and across the life-course (4).

The double burden of malnutrition poses a significant public health challenge to countries in the Region who are grappling with the unfinished agenda of undernutrition.

There is a definite relationship between undernutrition and overweight and obesity, which is beyond a mere coexistence. Epidemiological and supportive evidence demonstrate that undernutrition early in life – and even in \textit{utero} – followed by rapid weight gain and an unhealthy lifestyle may predispose the individual to overweight and NCDs in the future. Overweight in mothers is also associated with overweight and obesity in their offspring. The complexities of malnutrition call for policies and interventions which take into account the changing nutritional landscape.

---

2 The WHO South-East Asia Region consists of 11 countries – Bangladesh, Bhutan, Democratic People’s Republic of Korea (DPR Korea), India, Indonesia, Maldives, Myanmar, Nepal, Sri Lanka, Thailand, and Timor-Leste. The total population of the Region is about 1.9 billion, or almost 29\% of the global population.

3 Micronutrient deficiencies are not covered in this publication.
Apart from the Global Nutrition Targets for stunting, wasting and low birth weight (5), a voluntary global target was set by the World Health Assembly in 2012 as a result of the growing concerns regarding the rising trends in childhood overweight and obesity. The target is no increase in childhood overweight by 2025. The global estimated prevalence of 5.3% in children under 5 years of age (baseline year, 2012) should not increase (5). A similar target, of no increase in childhood overweight, has been set by the WHO South-East Asia Region, along with targets for stunting, wasting and low birth weight (3).

1.1 Global and regional nutrition targets and their current status

The global nutrition targets and their current regional status (3, 6, 7) are shown in Fig. 1.1. The figure includes indicators and estimated baselines. The baseline in each case is the status in 2012.

Sustainable Development Goal (SDG) 2 and Target 3.4 of SDG 3 are relevant here and are shown in Fig. 1.2 (8)

**Fig. 1.2**  Sustainable Development Goals and relevant targets

**Target 2.2:** By 2030, end all forms of malnutrition, including achieving, by 2025, the internationally agreed targets on stunting and wasting in children under 5 years of age, and address the nutritional needs of adolescent girls, pregnant and lactating women and older persons.

**Indicators:**

2.2.1 Prevalence of stunting from the median of the WHO Child Growth Standards among children under 5 years of age

2.2.2 Prevalence of malnutrition (weight-for-height > +2 or < -2 SD from the median of the WHO Child Growth Standards) among children under 5 years of age, by type (wasting and overweight)

**Target 3.4:** By 2030, reduce by one-third premature mortality from noncommunicable diseases through prevention and treatment and promote mental health and well-being.

The national targets adopted by countries regarding child overweight/obesity, stunting, low birth weight and wasting are given in Table 1. Six countries have set national targets for child overweight.

1.2 NCD targets and indicators relevant to childhood obesity

The Global NCD target, Halt the rise in diabetes and obesity (Target 7) and the physical activity target along with their relevant indicators are given below. (Fig1.3) (20, 21). The WHO global monitoring framework for NCDs calls for a 10% reduction in physical inactivity by 2025, and sets a minimum target of physical activity for adolescents (6). This emphasizes the fact that both healthy diets and physical activity are important components of a healthy lifestyle essential for reducing the risk of NCDs.

![Fig. 1.3 Global NCD targets on obesity and physical activity](image)

- **Global voluntary NCD target 7**
  - Regional status: Off track
  - Baseline (2015 at regional level): * 5.4%
  - Current status (2017): 8.1% (adjusted according to data for 2017)
  - Target (2030): 5.4%

### Indicators

- **Indicator 13**: Prevalence of overweight and obesity in adolescents
- **Indicator 14**: Age standardized prevalence of overweight and obesity in persons of the age of 18+ years

- **Age-standardized prevalence of insufficiently physically active persons aged 18+ years**: defined as less than 150 minutes of moderate-intensity activity per week, or equivalent

---

**a** Baseline at regional level set in 2015.

**b** Indicator 13: defined according to the WHO growth reference for school-aged children and adolescents; overweight – 1 SD from median BMI for age and sex, and obese –2 SD from mean BMI for age and sex

Indicator 14: BMI = 25 kg/m² for overweight and BMI = 30 kg/m² for obesity is also relevant because childhood obesity tracks into adult obesity and early actions are advisable.

**c** Prevalence of insufficiently physically active adolescents, defined as less than 60 minutes of moderate to vigorous intensity activity daily. Physical activity in 18+ years is also relevant since physical activity habits should be inculcated from an early age.
Methodology of data analysis

2.1 Defining childhood overweight and obesity and other anthropometric indicators

This report explores the double burden of malnutrition, presenting data on overweight and obesity among children of 0–19 years of age, as well as on stunting and wasting/thinness across the same age group. The estimates (point prevalence of different indicators) have been presented by three age groups: under 5 years (0–59 months), 5–9 years and 10–19 years. In addition, the mean BMI (kg/m²) is given for children of the age of 5–9 years and 10–19 years.

Table 2.1 presents the definitions of overweight and obesity, wasting/thinness and stunting used throughout this publication. These are based on WHO Child Growth Standards 2006 for children under the age of 5 years and WHO growth reference data 2007 for those of 5–19 years of age. Specific weight-for-length cut-offs are used to define overweight among for children under 5 years of age, while age-specific BMI cut-offs are used for children of 5–19 years of age (22, 23).

*Wasting is used to characterize children under 5 years of age with low weight for length/height, while thinness is used to characterize children of 5–19 years of age with low weight for length/height.
2.2 Data sources and processing

Data on the prevalence of overweight or malnutrition and on BMI are generally collected as part of representative, population-based, nationwide household sample surveys. These involve the anthropometric measurement of the height and weight of the individual, using standardized methods and equipment. Given the traditional focus of nutritional indicators in children under 5 years of age and on overweight and obesity among adults in relation to NCDs, the data availability for measurement of obesity and overweight varied across age-groups.

Most countries in the Region have been carrying out population-based surveys for more than two decades and had conducted at least two rounds of such surveys by 2019. However, traditionally, most of these surveys, such as demographic and health surveys (DHS) and multiple indicator cluster surveys (MICS), primarily collect anthropometric data for children under 5 years of age and for women (of the age of 15–49 years), and in recent years, for men (of the age of 15–59 years) in some countries. Further, all countries have been conducting national integrated NCD risk factor surveys (WHO STEP surveys or similar) that collect anthropometric data for adults in the age range of 15–64 or 15–69 years.

In addition to these integrated surveys, which collect anthropometric data along with data on other key public health conditions/programmes relevant to these population groups, many countries in the Region have started carrying out stand-alone comprehensive national household surveys on food and nutrition or micronutrients, covering an extensive age range. In recent years, Bhutan, India, Myanmar, Nepal and Timor-Leste have undertaken national nutrition surveys. Table 2.2 describes the data sources used for this publication.

Appendix 1 lists the national surveys of countries that collected anthropometric data for children under 5 years of age. Data from these surveys were used to assess the trends in malnutrition among children under 5 years of age. A relatively recent estimate was available for all countries as almost all have carried out at least one such survey in the last five years (2014–2019).

India is the only country that had population-level anthropometry data from a national survey that included the age groups of 5–9 and 10–19 years, in addition to the standard 0–4 years. (Appendix 1) Myanmar and Sri Lanka reported anthropometry data for 5–9-year-olds and Nepal for 10–19-year-olds. (Appendix 2) Data availability was least for the age group of 5–12 years, as this group was neither the focus of DHS/MICS, nor of NCD risk factor surveys that cover the age range of 15–69 years, nor of adolescent/youth surveys (Global School-based Health Surveys, or GSHS) that usually cover the age group of 13–17 years. (Appendix 3)

For 5–19-year-olds, this analysis used the data and estimates compiled as part of the NCD-RisC project in 2016 (24). The NCD-RisC project used pooled analysis from 2416 studies across the world and generated estimates from 1975 to 2016. Therefore, for most countries, a limitation was that the data for 5–9-year-olds and 10–19-year-olds was largely based on estimations. These estimates were either from some special studies or from neighbouring countries or regions. Appendix 2 lists all the studies from the Region used in this report.

As described in the NCD-RisC (24), the prevalence and mean BMI were estimated by conversion (or cross-walking regressions) with independent predictor variables, such as age, sex and the country’s income, with the help of a hierarchical structure of the statistical model consisting of country, region, super-region and world. In the hierarchical structure, the estimates for each country and year were informed by its own data (which were not available for most countries in the Region), and by data from other years in the same countries, or from other countries, especially in the same Region. As shown in Appendix 2, only India, Myanmar and Sri Lanka provided representative data for the age group of 5–9 years.

Only India and Nepal reported data on the age group of 10–19 years from population-based surveys. Some additional data were available through the GSHS conducted among schoolgoing adolescents of the age of 13–17 years, as well as from DHS/MICS surveys for the age group of 15–19 years. The data from these surveys were taken into account for the computation of estimates for the age group of 10–19 years under the NCD-RisC project, as shown in Appendix 2. Data on thinness in children of the age of 5–19 years were obtained from the Global Health Observatory for all countries, except those that had conducted recent surveys, as described above (25).
2.3 Calculation of aggregate weighted Regional estimates

In addition to individual country-level estimates, aggregated estimates are available for the WHO SEA Region. The Joint Child Malnutrition Estimates are developed by the UNICEF/WHO/World Bank interagency team, and global and regional estimates of malnutrition (stunting, wasting and overweight) in children under 5 years of age are updated annually. The last update was provided in March 2020 for the year 2019 (1).

All publicly available MICS and DHS, along with anthropometric data for the full range of 0–59 months of age, were reanalysed to produce standardized estimates over time. Regional trends in overweight among children of 5–19 years of age from 1990 to 2016 have been presented on the basis of the NCD-RisC data.

A regional prevalence combining national surveys was generated by applying population proportions in each country on the basis of the population estimates for the year 2020 from the United Nations World Population Prospects 2019 (26).
Malnutrition: regional and country status

As of 1 July 2020, the Region is estimated to have more than 700 million children (0–19 years of age), including approximately 169 million under 5 years of age (1, 24). The following sections present data on child malnutrition in the Region. Data on overweight and obesity is presented across three main age groups: under 5 years (0–59 months), 5–9 years and 10–19 years. Data on stunting and wasting are shown to highlight the double burden of malnutrition at the regional and national levels, and to emphasize the need for simultaneous actions to address childhood overweight within the existing programmes and beyond.

3.1 Regional prevalence and trends in malnutrition

The double burden of malnutrition is characterized by the coexistence of undernutrition with overweight, obesity or diet-related NCDs, in individuals, households and populations, and across the life-course (4). While childhood overweight is rising, undernutrition remains a significant public health problem in almost all countries. Almost one in three children under 5 years of age is stunted and one in seven is wasted (Fig. 3.1). However, the numbers and percentages have declined from the estimated 2012 levels. In 2019, the number of stunted children amounted to 52.6 million (31.0%), while the number wasted were 24.9 million (14.7%).

Fig. 3.1 Prevalence of stunting and wasting and estimated numbers affected in children under 5 years of age (2019)

Source: Adapted from the Joint Malnutrition Estimates 2020 with additional sources (Appendix 1)
Among older children too, while the prevalence of overweight is rising, more than one in five children in the age groups of 5–9 and 10–19 years remain thin for their age (Fig. 3.2). This double burden of malnutrition in terms of increasing levels of overweight and obesity and a slow reduction in stunting and wasting has significant implications for policy choices and actions by Member States.

**Fig. 3.2** Regional trends in overweight, stunting, wasting/thinness in children, by age group (1990–2019)

---

### 3.1.1 Childhood overweight and obesity

In 2019, 3% of children under 5 years of age (~5 million) in the Region were estimated to be overweight, compared to the global average of 5.6% (~38.3 million) (1). The prevalence of overweight among older children (5–19 years of age) was nearly double that among younger children (24). As shown in Fig. 3.3a, in 2016, almost 7.4% of children of the age of 5–9 years (global average 20.6%) and a similar proportion (7%) of 10–19-year-olds were overweight (compared to a global average 17.3%). Assuming that there was no increase or decrease in the prevalence of overweight between 2016 and 2020, this would imply that 12.7 million 5–9 year olds and 25.6 million 10–19 year olds are overweight in 2020, based on the population projection with medium fertility variant for 1 July 2020 from the UN World Population Prospects 2019 (26).

---

*Population weighted regional estimates were calculated from the NCD-Risc project national estimates for all countries, with two exceptions. For India, the National Nutrition Survey 2016–2018 was used, while for Nepal, the prevalence of overweight and obesity in the age group of 10–19 years reported in the Nepal National Micronutrient Survey 2016 was used.*
Overall, this amounts to almost 43.4 million children of the age of 0–19 years being overweight. Thus, the Region accounts for an estimated 13% of the global burden of 38.3 million overweight children under the age of 5 years and 11.3% of the global burden of 340 million overweight 5–19-year-olds.⁵

There has been a consistent increase in the trends in overweight and obesity since the 1990s with respect to children in the Region (Fig. 3.3b, 3.3c). However, the rate of increase appears to be much higher among the age groups of 5–9 years and 10–19 years. In addition, the increasing trend appears to have accelerated since 2010 among the older age groups. Achieving the Regional Nutrition Target 4 to halt the rise in obesity in children under 5 years of age by 2025 is in doubt, as also the NCD regional target of halting the increase in obesity (1, 7).

The increasing prevalence of overweight and obesity in the older age groups is reflected in the increasing trends in the mean BMIs of these groups between 1990 and 2016 shown in Fig. 3.3c. In the age group of 5–9 years, the mean BMI increased from 13.7 kg/m² in 1995 to 14.9 kg/m² in 2016, while in the age group of 10–19 years, it increased from 17.2 kg/m² to 18.3 kg/m².

### 3.2 National prevalence and trends in malnutrition

It is not only the relatively high level of overweight among children in most countries, but also the consistent increase in the trends of overweight since the 1990s that is of concern (Figs 3.4 and 3.5). The trends appear to have accelerated in many countries since

---

⁵ Worldwide, 38.3 million children under the age of 5 years were estimated to be overweight in 2019 (UNICEF JME, 2020) and 340 million of the age group of 5–19 years were estimated to be overweight in 2016 as per NCD-RisC.
**Fig. 3.3b** Regional trends in overweight in children by age group (1995–2016)

Data sources:
1. For 0–59 months, the Joint Malnutrition Estimates 2020 (JME 2020); most up-to-date national surveys, if not already in the JME 2020 (Appendix 1)
2. For 5–9 and 10–19 years: NCD-RisC for 2016; (Appendix 2) regional prevalence re-estimated with most recent national survey data from India and Nepal; (Appendix 1)

**Fig. 3.3c** Regional trends in mean BMI in the age groups of 5–9 years and 10–19 years (1995–2016)

![Graph showing regional trends in mean BMI in the age groups of 5–9 years and 10–19 years (1995–2016)](image)

Data source: NCD-RisC project estimates

Mean BMI is not presented for under 5 children, as overweight prevalence is estimated on the basis of weight-for-length cut-offs.
2010, specially in children aged 5–9 and 10–19 years. Many countries are not on track for achieving the Global and Regional Nutrition Target for childhood overweight.

Stunting among children under 5 years of age is declining in most countries, with some on track to achieve the global target on stunting (Fig. 3.4). Unlike stunting, the trends in wasting appear to be stagnant and have not shown significant improvement since the year 2000 or thereabouts.

Fig. 3.4  Trends in overweight, stunting and wasting in children under 5 years of age across countries (1986–2019)

Data sources: JME 2020, in addition to the most up-to-date national surveys not already in JME 2020 (Appendix 1)
In older children aged 5–19 years the estimated trends in thinness indicate a slow decline, while overweight is rising rapidly (Fig. 3.5). In some countries, the estimated prevalence of overweight was higher than that of thinness in 2015 (the latest year for which data were available). Stunting and wasting/thinness continue to dominate the malnutrition burden in all 11 countries, notwithstanding the increasing numbers of overweight children (Figs 3.4 and 3.5).

**Fig. 3.5** Trends in estimated prevalence of overweight and thinness in children of the age group 5–19 years in WHO South-East Asia Region (1975–2016)

Data source: NCD-RisC (Appendix 2)
In children under 5 years of age, Timor Leste reports the highest prevalence of stunting, with 45.6% of children stunted. However, in numbers, the greatest burdens are in India, Bangladesh and Indonesia (1). The latest national data for children under 5 years of age (Fig. 3.6) indicate the existence of multiple forms of malnutrition among young children.

**Fig. 3.6** The double burden of malnutrition in children under 5 years of age, by country

Data source: JME 2020, in addition to the most up-to-date national surveys not already in JME 2020 (Appendix 1)
3.2.1 Prevalence and trends in overweight

As shown in Fig 3.7, though the regional prevalence of overweight among children under 5 years of age is 3%, there are substantial intercountry variations to be considered. The data in Fig 3.7 are based on the most recent population-based surveys conducted within the last five years. While over 6% of children under 5 years of age were overweight in Thailand, Indonesia and Maldives, the prevalence of overweight was less than 2.5% in Bangladesh, Democratic People’s Republic of Korea, India, Myanmar, Nepal and Sri Lanka. The remaining countries, Bhutan and Timor-Leste, reported intermediate levels of 2.5%–6%.

![Fig. 3.7 Prevalence of overweight in children under 5 years of age, by country](image)

Data source: JME 2020, in addition to the most up-to-date national surveys not already in JME 2020 (Appendix 1)

The estimates produced by NCD-RisC for the year 2016 showed similar intercountry variations in children in the age groups of 5–9 and 10–19 years (Figs 3.8a and 3.8b). While the average prevalence of overweight among children aged 5–9 years at the regional level was 7.4%, it was less than 10% in three countries (India, Myanmar and Sri Lanka) where recent survey data was available. The Democratic Republic of Korea and Thailand were estimated to have a prevalence greater than 25% (Fig. 3.8a). For 10–19 year old children too, actual survey data is only available for India and Nepal (Fig 3.8b). The wide confidence intervals reflect the fact that actual survey data are scarce for the older age groups (see methodology).
The double burden of malnutrition: priority actions on ending childhood obesity

3.2.2 Overweight and stunting at individual and household levels

Multiple combinations of anthropometric deficits exist in individuals and households. These include the coexistence of overweight and stunting in children, as well as pairs of overweight mothers and stunted children. Fig. 3.9 depicts the overlapping of stunting and overweight in children under 5 years of age in select countries.

### 3.3 Sociodemographic and economic variations in child overweight

#### 3.3.1 Age

The importance of focusing on the prevention of early-life obesity is underscored by WHO’s Ending Childhood Obesity Report, since the development of obesity may well be initiated during infancy and early childhood (27). In children under 5 years of age, disaggregation of the data by age showed that during 2016–2019, the prevalence of overweight among children of 0–23 months of age was higher (almost double) than that in the 24–59 month age group in all countries, except Thailand, where the pattern was reversed (Fig. 3.10). This aspect needs further exploration.

In all countries, the estimated prevalence of overweight in the age group of 5–9 years was higher than that among children under 5 years of age. In countries where recent survey data were available, (India and Nepal) the prevalence continued to increase with age. Though the estimated prevalence of overweight was the highest among 5–9-year-olds, the data for this age group need to be validated by future surveys since national-level survey data were available only for India, Myanmar and Sri Lanka. In India, the pattern was different and the prevalence of overweight was the highest in the age group of 10–19 years. India’s data is most likely a more accurate representation of the status across many countries, since the information on both age groups (5–9 and 10–19 years) is based on recent national survey data rather than estimates from the NCD-RisC project. In Myanmar and Sri Lanka too, where national survey data were available, the prevalence among the age group of 5–9 years was lower (actual data) than among the age group of 10–19 years (estimates).

3.3.2 Sex

Globally, information on overweight and obesity in childhood shows sex differences to be inconsistent. As shown in Fig. 3.11a, sex differentials in overweight among children under 5 years of age were not significant, either in terms of absolute percentage or in statistical terms, except in Maldives. The data presented in Fig. 3.11 b for the age group of 15–19 years from STEP surveys in Bangladesh, Bhutan and Nepal are not adequate to draw a conclusion. The NCD-RisC estimates for the age groups of 5–9 years and 10–19 years, presented in Figs 3.12a and 3.12b, show that male children were somewhat more likely to be overweight. However, the differences between male and female were not significant.7

3.3.3 Urban/rural residence

The proportion of urban population is increasing consistently in most countries in the Region and is likely to overtake the rural population in the next two to three decades (26). The urban environment is more likely to be obesogenic because it offers greater access to and availability of energy-dense processed foods, is less enabling for physical activity, and encourages a sedentary lifestyle (27, 28).

As expected, urban children under 5 years of age were significantly more likely to be overweight than rural children, except in Bhutan and Maldives, where reverse patterns were seen. (Fig. 3.13 a) In many countries, the prevalence of overweight in urban areas was almost two times or more than that in rural areas (Fig. 3.13b). This trend was also evident among children in the age group of 15–19 years.

In India, where actual survey data were available for the age groups of 5–9 and 10–19 years, similar patterns were reported. Among 5–9-year-olds, 7.5% urban children were overweight, compared to 2.6% rural children. Urban adolescents of 10–19 years of age were more than three times as likely to be overweight than rural children (9.7% vs 3.2%). The trend was reversed in the case of thinness: the prevalence of thinness was likely to be greater among rural children than urban children (Fig. 3.14).
The double burden of malnutrition: priority actions on ending childhood obesity

Data source: for children < 5 years see appendix 1; for 15–19 years see Appendix 3

* DHS data only analyzed for girls

Data source: Comprehensive National Nutrition Survey 2019 (Appendix 1)
3.3.4 Household wealth

Lifestyles in the Region have been redefined by rapid economic development (Fig. 3.15), with the influx of wealth and resources affecting dietary patterns, transportation and social norms (28, 29). Energy-dense food such as highly processed, packaged and fast food and vehicular transport are more accessible to higher income groups, possibly contributing to child and adult obesity. The prevalence of childhood overweight at all ages appears to be the highest in Thailand, Maldives and Indonesia, which have comparatively higher levels of gross national income per capita.

**Fig. 3.15** Gross national income per capita growth in select countries

![Gross national income per capita growth in select countries](image)

Data source: World Bank 2020 (30))

At the household level, children in the poorest households were less likely to be overweight than those in the richest households in almost all countries, except Timor-Leste, where no clear trend emerged (Figs 3.16a and 3.16b). Reverse trends were seen for stunting and wasting, which had a higher prevalence in the poorer households. However, an important point to be noted is that child overweight has started to emerge even among the poorest two quintiles.
In India, where recent survey data were available for older children, similar differentials by household wealth were seen. In the age group of 5–9 years, children in the richest quintile were almost eight times more likely to be overweight than those in the poorest quintile. In the age group of 10–19 years, the differentials widened further: 11.6% in the richest quintile versus 0.8% in the poorest (Figs 3.17a and 3.17b). Reverse trends were observed for thinness. Thus, overweight is dominant in the richest quintile, while undernutrition dominates in the poorest quintile.
3.3.5 Maternal education

The level of maternal education may have a bearing on household wealth. It may also have an independent protective effect on both underweight and overweight because an educated mother is likely to have more information and knowledge regarding diets and lifestyle. However, among children under 5 years of age and girls of the age of 15–19 years, those whose mothers had higher levels of education were more likely to be overweight than children whose mothers had no education, except in Maldives and Thailand (Figs. 3.18a, 3.18b). This is possibly because education is tied with income, where more educated mothers are generally from high-income groups and are more likely to be living in urban areas.
Data source: For 0–59 months of age, see Appendix 1; for 15–19 years of age, see Appendix 3

*DHS data analyzed only for girls
4.1 Health and economic effects of malnutrition

Good nutrition is critical to health and economic development. The effects of undernutrition on health and economic development consist of delayed child development, greater susceptibility to infections, poor school performance and lower earnings in adulthood (29). Children who suffer from undernutrition early in life and are then exposed to obesogenic environments are at a greater risk of overweight, obesity and diet-related NCDs, increasing the economic burden on individuals and on health systems (27, 29).

Though undernutrition remains a major concern, policy-makers and national governments should pay attention to the relatively rapid transition from underweight to overweight and obesity in low-income and middle-income countries. The double burden of malnutrition adds an additional layer of complexity and the speed of the transition to overweight/obesity can tax a nation’s capacity to effect a healthier transition (29, 31).

4.1.1 Health consequences of overweight and obesity in childhood

The excess body fat in an overweight or obese child is associated with an elevated risk of metabolic syndrome at a young age, and of being an overweight or obese adult, who is more susceptible to NCDs such as cardiovascular disease and diabetes (32, 33, 34). The most significant health consequences of childhood overweight and obesity that may not become apparent until adulthood include cardiovascular diseases (mainly heart disease and stroke); diabetes; musculoskeletal disorders, especially osteoarthritis; and certain types of cancer (endometrial, breast and colon). These are associated with lifelong morbidity and often, premature death. About 8.5 million people in the Region die of NCDs every year (62% of all deaths), and many of these deaths are premature (33).

It is a matter of concern that in some countries, there is evidence that points to an increased risk of metabolic derangement even among children who are not yet at the BMI-for-age threshold for the current definition of childhood overweight attributed to excess body fat (34, 35, 36).
The double burden of malnutrition: priority actions on ending childhood obesity

Fig. 4.1: Health consequences of childhood overweight and obesity

- Poorer health in childhood including hypertension and metabolic disorders
- Higher likelihood of being bullied
- Poorer school attendance levels and poorer school
- Poorer health in adulthood including a higher risk of obesity
- Poorer employment prospects as an adult

4.1.2 Economic consequences

The economic and developmental costs of overweight and obesity are considerable because of the association of these conditions with a higher risk of chronic disability and premature death in adulthood (37).

Table 4.1 presents the disability-adjusted life year (DALY) estimates and the total productive years lost due to overweight and obesity for a specified time horizon (37). The number of total productive years lost due to overweight and obesity (approximately 1.77 million) was the highest in India, followed by Indonesia (756 000) and Myanmar (99 000). It is evident that preventing childhood obesity would result in significant health and economic benefits to individuals, families and countries.

* The author’s strategy for estimating the indirect cost of overweight and obesity is largely based on the years of life lost due to premature death and the years of life lost due to disability. The estimation includes eight diseases attributable to high BMI: (1) ischaemic heart disease, (2) stroke, (3) diabetes, (4) liver cancer, (5) breast cancer, (6) oesophagus cancer, (7) gall bladder and biliary tract cancer, and (8) hypertensive heart disease.
4.2 Drivers of the double burden of malnutrition in children

The biological, environmental, social and behavioural factors driving the double burden of malnutrition in the Region are undoubtedly interlinked.

- Maternal stunting, underweight and inadequate weight gain during pregnancy may restrict intrauterine growth, which is associated with an increased risk of stunting and NCDs (38).
- The exposure of children who have inadequate biological and/or behavioural responses to an unhealthy obesogenic environment due to in utero insults, such as poor nutrition, increases their odds of being overweight (39).
- Severe undernutrition (stunting, wasting) in early childhood may continue to deplete the metabolic capacity of children and increase their susceptibility to overweight, obesity and NCDs (40, 41).

These responses vary among individuals and are strongly influenced by developmental factors or factors related to the life-course, as shown in Fig. 4.2.

Policy-makers in countries should be aware of the complex and multifaceted nature of the challenge they are facing. A thorough knowledge of the main risk factors and determinants of overweight/obesity in the country is of key importance for the development of targeted interventions. Select drivers of child overweight and obesity in the Region are shown below.

4.2.1 Biological and individual factors

Nutritional status of mother

The offspring of overweight and obese women have an increased risk of being born large for gestational age and tend to become overweight or obese as children (38, 40). A woman’s pre-pregnancy weight and epigenetic influences, even from the prior generation, pose a risk for the child. The chances of being overweight increase as the child grows older – a reflection of exposure in utero as well as during the life-course (38, 39, 41).
It is a matter of concern that some pre-pregnant and pregnant women in the Region are likely to be overweight (Fig. 4.3), increasing the risk of obstetric complications for the mother, and later, obesity in the offspring. As shown in the figure, a substantial number of women of reproductive age are also thin, which is not only a risk factor for low birth weight and stunting, but also for NCDs and obesity.
Fig. 4.3  Nutritional status in women of reproductive age (15–49 years)

Fig. 4.4 shows the trends in overweight and obesity by age group. The prevalence of overweight tends to be higher among older women, but even among women in the age groups of 20–29 years and 30–39 years, among whom pregnancy is most likely, a significant percentage are overweight. Therefore, current policies for antenatal care, including interventions such as dietary counselling and food supplementation, need to be revisited and redesigned through the adoption of a more targeted approach.

Fig. 4.4  Prevalence of overweight in different age groups among women of reproductive age, in select countries
Low birth weight

Birth weight is an indicator of a newborn’s well-being and is a proxy measure of the intrauterine environment and the nutritional status of the mother during pregnancy. Children born with low birth weight are at a greater risk of stunting. Low birth weight is also associated with an increased risk of overweight/obesity when accompanied by energy-dense diets and a sedentary lifestyle later in life (43). Of all the WHO regions, the South-East Asia Region has the highest estimated prevalence of low birth weight. Almost a quarter (24.2% [16.4–32.1]) of the children are born with low birth weight. This places these children at a higher risk of neonatal morbidity and mortality, stunting and NCDs (2). Table 4.2 shows the estimated prevalence of low birth weight by country.

Young children’s diet and feeding practices

The diets of infants and young children in the Region are often suboptimum, resulting in stunting, wasting or overweight. It is not only the overconsumption of food and increase in sedentary behaviour that induce overweight. Stunting too can place children at an especially high risk of developing obesity when patterns of diet and physical activity change. The fact that the prevalence of overweight was found to be higher among younger children in the age group of under 5 years indicates that more attention needs to be paid to optimizing the diets of very young children.
Breastfeeding is clearly a protective factor against both undernutrition and obesity (27). While many countries in the Region have high levels of breastfeeding, (Fig. 4.5), further improvement in breastfeeding will provide protection against stunting, wasting, micronutrient deficiencies as well as future overweight.

![Fig. 4.5](image)

**Fig. 4.5** Trends in exclusive breastfeeding in infants 6 months of age, by country

Data source: JME 2020, in addition to the most up-to-date national surveys not already in JME 2020 (Appendix 1); Indonesia: DHS 2017

Children of the age of 6–23 months and older can suffer lifelong consequences if they have diets that lack diversity and are inadequate in quantity (44). More and more young children are being fed foods that are high in sugar and fat and low in essential nutrients. Poor diets are a problem, as shown by the proportion of children receiving appropriate diets (Fig. 4.6).  

Recent data from Nepal’s National Micronutrient Survey (Appendix 1) provide an example of energy-dense, nutrient-poor foods often provided to young children of the age of 6–59 months (Table 4.3).

---

8 Appropriate feeding, defined as the percentage of children receiving appropriate nutrition, is calculated by taking into account the current guidelines on the number of food groups and the number of times a child should eat during the day or night preceding the survey (46).

Diet, physical activity and sedentary behaviour patterns of older children

Data on older children, obtained from the GSHS, provide evidence of unhealthy lifestyles, poor diets, low levels of physical activity and sedentary behaviour (Table 4.4). Far too many schoolgoing children are eating too few fruits and vegetables, and consuming unhealthy snacks that are high in sugar, saturated fat and sodium. These are often marketed to and popular among schoolgoing children. The levels of physical activity among children have not been reported at the national level. However, a review of studies on the prevalence of physical activity has found that the rates of physical activity among Asian schoolgoing children and adolescents of the age group 7–19 years are low (45). This is affirmed by Table 4.5.

4.2.2 Factors at household, community and environmental levels

Food environment

An increase in the availability and accessibility of high-energy foods and beverages, together with aggressive marketing of such products, has contributed to the creation of an obesogenic food environment. Select examples of the changing food environment in terms of the affordability of sugar-sweetened beverages and the increasing sales of these beverages in the Region are provided in Figs 4.7a, 4.7b and 4.7c (46, 47,48).
Fig. 4.7a  Trends in consumption of sugar-sweetened beverages in Sri Lanka (base 2009=100)

Fig. 4.7b  Real price of sugar sweetened beverages (off trade channel) in Bangladesh (Base 2004=100)

Data source: Based on Euromonitor International and Bangladesh Bureau of Statistics
Marketing of foods that are high in sugar and fat and of nonalcoholic beverages to children has been recognized as a factor that contributes to obesogenic food environments and the consumption of unhealthy diets. In 2010, the Sixty-third World Health Assembly endorsed a set of recommendations on the marketing of foods and nonalcoholic beverages to children (WHA63.14) and urged countries to reduce the impact of marketing on children (49). Figs 4.8a and 4.8b provide information on the marketing of foods and beverages to children in India and Sri Lanka. The category of food for children that was the most advertised on television consisted of confectionary items and bakery wares, such as biscuits (50, 51).
Fig. 4.8b Volume of advertisements on high-fat, sugar and salt products on media during a one-month period in India

Data source: WHO technical report (51)

4.2.3 The built environment and opportunities for physical activity

The Lancet Commission on Obesity draws attention to the important contribution of the built environment to the obesogenic environment (52). Giving priority to pedestrians and access to pavements and green spaces is important. It is also necessary to ensure that schools have playfields, and the school curriculum supports physical activity. In the crowded, population-dense cities in the Region, innovative thinking is required to make provisions for these requirements. Improving physical activity, reducing sedentary time and ensuring quality sleep in young children will improve their physical, mental health and wellbeing, and help prevent childhood obesity and associated diseases (27). For children, physical activity includes play, games, sports, transportation, chores, recreation, physical education, or planned exercise, in the context of family, school, and community activities (53). Physical activity improves cardiorespiratory and muscular fitness, bone health, and cardiovascular and metabolic health biomarkers. Table 4.4 shows the inadequate levels of physical activity and concerning levels of sedentary behaviours in children.

4.3 Country policy measures that address aspects of the double burden

The current status of some of the policies implemented by countries to reduce the double burden of malnutrition are provided in the section on each country’s nutrition profile (Annex 4). Policies that address undernutrition are generally robust. Most countries have identified and are implementing recommended evidence based interventions to tackle undernutrition, but those that address overweight, obesity and NCD risk are few.
The way forward: actions to address overweight and obesity

As countries in the Region progress through the stages of demographic, lifestyle and nutrition transition associated with economic development, globalization and urbanization, the changing malnutrition profiles are clearly evident. The high middle-income countries and/or those which are relatively more urbanized tend to have a higher burden of child overweight and a lower burden of stunting and wasting. The prevalence of stunting and wasting/thinness is high in the low-income and low-middle-income countries (Bangladesh, India, Nepal). However, these countries are also showing rising trends in child overweight.

The data presented in the preceding chapters show the extent of the double burden of malnutrition in children and evidence for some of its drivers. Considering the lifecycle, maternal nutrition is of concern with a significant level of thinness and overweight in women of reproductive age. Low birth weight, a key risk factor for later NCDs is higher compared to other Regions, with almost a quarter of children being born weighing < 2500 g. Across countries, almost half the infants and young children are not exclusively breastfed and complementary feeding practices are poor. The selected data on dietary intake of school children, the sedentary behaviours and information on marketing and sales of sugar sweetened beverages are indicators of poor quality dietary intake and suboptimal dietary environment that drives the multiple forms of malnutrition.

Children are affected by their early developmental conditions, with long-term consequences. Children’s food habits, tastes and preferences are formed in early childhood and continue into adulthood, supporting the argument that early interventions are vital for healthy growth. Along with healthy dietary habits, the importance of physical activity from the earliest age is well known and has been emphasized by the Commission on Ending Childhood Obesity (27). WHO recommends that to grow up healthy, young children need to sit less and play more (54). For older children, WHO recommends that adequate facilities should be available on school premises and in public spaces for physical activity during recreational time for all children (including those with disabilities), with the provision of gender-friendly spaces where appropriate (53).

The need to intervene early is obvious. Given the exponential rise in the risk of NCDs through the life course, the most effective means of reducing the risk of NCDs is to undertake timely preventive measures and intervene as early as possible to reduce the double burden of malnutrition (55).
5.1 Shared drivers and use of common platforms

Overweight and undernutrition share common drivers, such as intergenerational linkages, environmental and socioeconomic influences as shown in the preceding chapters. Therefore, countries in the Region could utilize existing platforms to scale up current interventions to address undernutrition and food insecurity, and, concurrently, implement actions to address overweight and obesity (56).

<table>
<thead>
<tr>
<th>COMMON PLATFORMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>• National policies for nutrition, NCDs</td>
</tr>
<tr>
<td>• National dietary guidelines</td>
</tr>
<tr>
<td>• Primary health-care programmes</td>
</tr>
<tr>
<td>• Regulatory, legislative and fiscal policies to promote a healthy food environment</td>
</tr>
<tr>
<td>• Social protection policies</td>
</tr>
</tbody>
</table>

The food culture and behaviours in the context of South-East Asia must also be taken into account when seeking solutions to the malnutrition crisis. Dietary patterns and habits in the Region differ from those in high-income countries. A large proportion of foods consumed in the former are home-cooked and from informal food vendors/stalls, especially in urban areas. The consumption of ultra-processed, packaged foods provided by the formal sector is lower, though increasing trends in sales of such foods are a sign that dietary patterns are changing. Therefore, action to promote healthy diets should address both formal and informal food sectors.

5.2 Potential regional strategies and way forward

The Strategic Action Plan to reduce the double burden of malnutrition 2016–2025, was endorsed by the Sixty-ninth session of the Regional Committee, in view of the increasing double burden of malnutrition and the urgent need to address the problem (3). The plan lays out a range of policy actions that countries could implement, under four strategic directions on governance, developing relevant guidance and legislations, strengthening health systems and community empowerment. Further directions have been provided by WHO through the policy brief for double duty actions and the ECHO implementation plan (56, 57). As described in the following pages, selected priority interventions are identified under each strategic direction.
**Strategic direction 1:** Improve nutrition governance through enhanced political commitment and evidence-informed context-specific sectoral policies and actions.

Undertaking advocacy with political and opinion leaders to enhance their understanding of the current trends in nutrition status and to consolidate investments for reducing obesity as well as undernutrition is vital. Advocacy with and messages for policy-makers need to be crafted carefully since substantially more children are stunted or wasted than overweight, and historically, the focus of the Region has been on undernutrition. It is of crucial importance to review, update and strengthen the national platforms through the identification of common policy and programmatic opportunities to address the double burden. The undernutrition agenda must continue to be scaled up, while adding on actions to prevent overweight, where applicable. Creating an enabling environment includes understanding the commercial determinants of child obesity, and implementing actions to counter conflict of interest in food and nutrition for public good. The emphasis on physical activity has to be enhanced. Strengthening the availability of data to underpin all processes is vital. The dearth of nutrition status data for older children, the inadequacy of dietary and physical activity data for children of all age groups, and on the food environment should be addressed.

**Actions**

- Ensure that overweight and obesity are addressed in nutrition policies, strategies and action plans. The links to NCD policies have to be made explicit, and action plans should be costed to ensure budgetary allocations.
- Set national, time-bound targets on reducing child overweight to the levels set out in the existing nutrition goals and targets.
- Gather quality data for evidence-informed policy-making and monitoring of policy progress. National surveys should be expanded to cover at least the age group of 5–9 years and must be conducted at regular intervals to study the trends and outcomes of interventions. To formulate appropriate policies, it would be useful to go beyond nationally representative anthropometric data disaggregated by sex, age, demographic details and socioeconomic status, and gather other information such as on micronutrient deficiencies, dietary intake and physical activity in children aged 5–19 years.
- Broaden the focus of multisectoral plans of action and multisectoral platforms on nutrition to include child overweight. An example is the broadening of social protection programmes to ensure that populations facing food insecurity are provided access to healthy diets.
- Review policies on food assistance and related programmes for maternal and child nutrition to ensure their sensitivity to child overweight. Preventing the risk of excessive energy intake and unhealthy weight gain is important, especially among populations undergoing a rapid nutrition transition. Programmes must provide foods that contribute to overall healthy diets, and not to increase obesity. Further, they should be revised to ensure delivery to only those who are in need.
**Strategic direction 2:** Develop or adopt relevant guidelines, legislation and regulatory frameworks needed to implement evidence-based interventions.

In trying to create an enabling environment to reduce the double burden of malnutrition, greater attention must be paid to country guidelines, and legislative and regulatory policies which address population-level risk factors (57). These policies must be sustainable and enforceable, and that their implementation should be monitored.

**Actions**

- Develop appropriate and context-specific nutrition information and develop and implement food based dietary guidelines for children.
- Enforce the International Code of Marketing of Breast-milk Substitutes and the guidance on Ending the Inappropriate Promotion of Foods for Infants and Young Children (58, 59). Establish mechanisms to effectively monitor and track their implementation.
- Develop and implement legislation or regulations on the marketing of foods and nonalcoholic beverages to children (49).
- Pass legislation and formulate policies on maternity leave and protection (including maternity benefits, leave and breaks for breastfeeding for women working outside the home).
- Implement fiscal policies that subsidize healthy diets and reduce the accessibility of unhealthy diets through measures such as imposing taxes on sugar-sweetened beverages (57).
- Introduce regulations on food labelling to enhance nutrition literacy and empower children to make healthy choices (57).
- Set dietary standards to create a healthy food environment in preschools and schools, keeping in mind the double burden of malnutrition (57).
- Establish regulations and standards for social support programmes that are based on national dietary guidelines.
- Set standards for food reformulation in partnership with industry to promote healthier nutrient profiles for commercially prepared foods (57).
- Identify and implement actions to encourage the informal food sector to promote healthy food. An example would be zoning regulations around schools which could restrict sales of specific foods.
Strategic direction 3: Strengthen health systems to address the double burden of malnutrition with adequate resources, capacity-strengthening and comprehensive monitoring and evaluation.

With countries undergoing a nutrition transition, planning a shared pathway for preventing malnutrition is important. The policies and programmes of health systems that focus on nutrition during critical periods in the life-course (preconception and pregnancy, infancy and early childhood, and older childhood and adolescence) can be expanded by introducing or scaling up double-duty actions (56). Relevant evidence-based recommendations are provided in WHO’s Essential nutrition actions: mainstreaming nutrition through the life-course (60). Gaps in the health system must be identified and remedial measures taken to enhance its capacity to effectively address undernutrition and overweight, obesity and NCDs concurrently.

Actions

- Allocate adequate resources, build the capacity of the staff and reorient to integrate actions to address overweight and obesity along with the ongoing actions to reduce undernutrition.
- Ensure that the relevant essential actions on nutrition, as recommended by WHO (58), are prioritized and included in universal health-care packages.
- Implement the WHO recommendations on preconceptional and maternal nutrition, including those on counselling on diet and nutrition, and the diagnosis and management of hyperglycaemia and gestational hypertension (61). Undernourished populations should be educated regarding dietary intake and assisted with balanced energy and protein food supplementation as appropriate.
- To optimize the development and growth of infants, promote, support and protect breastfeeding. Infants should be exclusively breastfed for the first six months of life, after which breastfeeding should be continued together with the introduction of appropriate complementary foods (62).
- Expand the existing programmes on the monitoring and promotion of growth to include overweight. This includes counselling of caregivers in responsive feeding and encouraging infants and young children to eat a wide variety of healthy foods (62).
- Implement the guidance on assessing and managing children at primary health-care facilities to prevent overweight and obesity in the context of the double burden of malnutrition faced by countries (63).
- Implement the recommendations on nutrition and related health measures for older children and adolescents, in accordance with the country’s context (57, 64). These include promoting healthy diets, iron folic acid supplementation of school children, managing acute malnutrition, preventing adolescent pregnancy and poor reproductive outcomes.
- Coordinate with NCD services to implement actions to reduce diet-related factors that increase the risk of NCDs (65).
- Implement the WHO guidelines on physical activity, sedentary behaviour and sleep for children under 5 years of age (54).
- Promote the implementation of the recommendations on appropriate physical activity for the age group of 5–17 years (66).
- Introduce referral services for monitoring growth for the management of overweight and obesity, in schools and through other appropriate delivery platforms (57).
- Introduce and support appropriate weight management services for children and adolescents who are overweight or obese. The services should be family-based and consist of various components, including nutrition, physical activity and psychosocial support (57).

**Strategic direction 4: Empower communities, support and strengthen academia and civil society to promote healthy diets, and form strategic alliances with stakeholders (56).**

**Actions**

- Create awareness among communities regarding the problem of overweight and obesity, i.e. the double burden. This will be a complex task, given that the information to date have focused solely on stunting and wasting.
- Obtain the entire community’s support for improving nutrition literacy and promoting healthy lifestyles among children and their families.
- Advocate for the establishment of a suitable built environment to promote physical activity.
- Strengthen community structures to empower women, families and communities to appreciate the importance of optimal care during pregnancy.
- Promote implementation research in the Region to create an understanding of how to scale up cost-effective multisectoral interventions that can tackle stunting, overweight and micronutrient deficiencies.
- Emphasize the importance of the shared family environment as a multifactorial contributor to childhood obesity problems and the necessity of implementing family-centred preventive programmes.
- Explore partnerships with the private sector to improve diets and to promote and support physical activity.
5.3 Conclusion

Halting the increase in overweight in WHO SEA Region countries is a possible but complex process, considering the Region’s burden of undernutrition. All aspects of malnutrition require consideration in both existing and future policies and programmes. Focusing on overweight and obesity in the context of South-East Asia requires careful planning and crafting of policies, following a comprehensive review of the situation within each country.

Carrying out a detailed mapping of current status of policies, which will provide information on strategic entry points to prioritize and implement childhood obesity actions, availability of double duty platforms to include interventions on overweight and obesity and identify needs to scale up actions to reduce undernutrition is vital.

This information will help address and identify the dearth of supportive policies across all sectors, including health, agriculture, transport, urban planning, environment, food access, distribution and marketing, and education sector. A dynamic, whole of government approach with well thought out policies, long term sustainable plans and investments are needed. Countries should shift towards an integrated strategy and broaden the focus of nutrition and health programmes to tackle the double burden of malnutrition and its drivers.

Considerations when implementing policy measures to improve nutrition status of children

- Do no harm through existing actions on undernutrition: Assess and ensure that current initiatives (for example, feeding programmes, financial policies that subsidize production of unhealthy food) are not inadvertently increasing the risk overweight obesity or NCDs.

- Retrofit existing nutrition actions: Examine actions that are already being implemented for their potential to positively and simultaneously influence overweight and obesity (for example, feeding in schools).

- Develop new actions: Assess evidence-based actions that are potentially the most context-specific for implementation in a particular setting. These should reflect the local epidemiology, policy, and cultural, environmental and food contexts. Some examples are regulations for the marketing of foods and beverages to children, and physical activity programmes.

The double burden of malnutrition: priority actions on ending childhood obesity

Nutrition status of children

**TARGETS**

**Global**

- No increase in childhood overweight
- 40% reduction in the number of children under-5 who are stunted
- Reduce and maintain childhood wasting to less than 5%

**Country**

- By 2023, Maintain the prevalence of overweight in children under-5 years to not more than 8%; Reduce the prevalence of overweight in 6-14 ye..
- By 2025, Reduce the prevalence of stunting in children under-5 years to ≤10%.
- By 2025, Reduce the prevalence of wasting in children under-5 years of age to ≤5%.

The nutrition transition: trends in overweight and undernutrition

**Fig10 Under 5 years**

- Stunting: 5.7% to 2.2%
- Wasting: 1.3% to 1.2%
- Overweight: 11.5% to 7.7%

**Fig11 5-9 years**

- Thinness: 10.6% to 7.7%
- Overweight: 28.8% to 20.4%

**Fig12 10-19 years**

- Thinness: 10.4% to 7.7%
- Overweight: 29.4% to 20.4%
